

## 1 Countability: True or False

- (a) The set of all irrational numbers  $\mathbb{R} \setminus \mathbb{Q}$  (i.e. real numbers that are not rational) is uncountable.
- (b) The set of integers  $x$  that solve the equation  $3x \equiv 2 \pmod{10}$  is countably infinite.
- (c) The set of real solutions for the equation  $x + y = 1$  is countable.

For any two functions  $f : Y \rightarrow Z$  and  $g : X \rightarrow Y$ , let their composition  $f \circ g : X \rightarrow Z$  be given by  $f \circ g = f(g(x))$  for all  $x \in X$ . Determine if the following statements are true or false.

- (d)  $f$  and  $g$  are injective (one-to-one)  $\implies f \circ g$  is injective (one-to-one).
- (e)  $f$  is surjective (onto)  $\implies f \circ g$  is surjective (onto).

## 2 Counting Cartesian Products

For two sets  $A$  and  $B$ , define the cartesian product as  $A \times B = \{(a, b) : a \in A, b \in B\}$ .

- (a) Given two countable sets  $A$  and  $B$ , prove that  $A \times B$  is countable.
- (b) Given a finite number of countable sets  $A_1, A_2, \dots, A_n$ , prove that

$$A_1 \times A_2 \times \dots \times A_n$$

is countable.

### 3 Undecided?

Let us think of a computer as a machine which can be in any of  $n$  states  $\{s_0, \dots, s_n\}$ . The state of a 10 bit computer might for instance be specified by a bit string of length 10, making for a total of  $2^{10}$  states that this computer could be in at any given point in time. An algorithm  $\mathcal{A}$  then is a list of  $k$  instructions  $(i_0, i_1, \dots, i_{k-1})$ , where each  $i_\ell$  is a function of a state  $c$  that returns another state  $u$  and a number  $j$  describing the next instruction to be run. Executing  $\mathcal{A}(x)$  means computing

$$(c_1, j_1) = i_0(x), \quad (c_2, j_2) = i_{j_1}(c_1), \quad (c_3, j_3) = i_{j_2}(c_2), \quad \dots$$

until  $j_\ell \geq k$  for some  $\ell$ , at which point the algorithm halts and returns  $s_{\ell-1}$ .

- (a) How many iterations can an algorithm of  $k$  instructions perform on an  $n$ -state machine (at most) without repeating any computation?
- (b) Show that if the algorithm is still running after  $nk + 1$  iterations, it will loop forever.
- (c) Give an algorithm that decides whether an algorithm  $\mathcal{A}$  halts on input  $x$  or not. Does your construction contradict the undecidability of the halting problem?

### 4 Code Reachability

Consider triplets  $(M, x, L)$  where

```
M is a Java program
x is some input
L is an integer
```

and the question of: if we execute  $M(x)$ , do we ever hit line  $L$ ?

Prove this problem is undecidable.
